

Question 1)

Part a)

Logical address is generated by CPU whereas Physical address is located in Memory Unit.

Logical Address space is a set of all Logical addresses generated by CPU in reference to a program whereas Physical Address is set of all physical addresses mapped to the corresponding logical addresses.

Users can view logical addresses but cannot visit physical addresses.

Part b)

In Large pages our Page table is smaller than the case that our pages are Small so finding the correspond page and after that corresponding frame is faster.

In Small pages our unused space is smaller than the case that our pages are Large and we say in small pages we have Internal fragmentation whereas in Large pages we say we have external fragmentation.

So in overall in the trade of Time and Place we say Large pages are better for Time and worse for Place (more unused place) whereas Small Pages are better for Place (less unused place) and worse for Time (more time required to search).

Question 2)

$$1EAF = \overbrace{0001}^{m-n} \underbrace{111010101111}_n$$

$$4KB = 4 \times 2^{10} = 2^{12}$$

$$\Rightarrow m=16$$

$$n=12$$

if we have standard logical to ~~exten~~^{physical} mapping of location then

So $\Rightarrow 10 \text{ EAF} \rightarrow \boxed{A \text{ EAF}}$

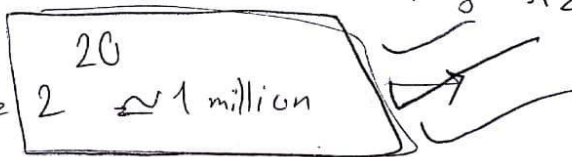

Question 3)

32-bit logical address $\rightarrow 2^{32}$

\downarrow
pointing to 2^{32} physical page frames

Each page size $\rightarrow 4\text{KB} = 2^{12}$ bytes

Number of Pages in Ptable $\frac{\text{Total possible logical address entries}}{\text{Page size}}$

$$= \frac{2^{32}}{2^{12}} = 2^{20} \approx 1 \text{ million}$$

Also as each entry in Page table is 4 bytes.

That means that the total size of the page table in physical memory is $4 \times 2^{20} = 2^{22} = 4\text{MB}$

Question 4)

Question (4)

Mem size \rightarrow 100, 500, 200, 300, 600

Process Size \rightarrow 212, 417, 112, 426

First Fit

	212	417	112	426
100				
500	212	212	212 112	212 417
200	<u>288</u>		<u>176</u>	
300				
600		417	417	417
		<u>183</u>		

So 426 is not allocatable in First Fit

Worst Fit

	212	417	112	426
100				
500		417	417	417
200		<u>83</u>		
300				
600	212	212	212 112	212 112
	<u>388</u>		<u>276</u>	

So 426 is not allocatable in WF

Best Fit

	212	417	112	426
100				
500		417	417	417
200		⁸³	112	112
300	212	212	212 ⁸⁸	212
600	⁸⁸			426
				¹⁷⁴

So in overall it is better to use BEST-FIT algorithm as if we use this algorithm in this scenario then we do not need to do a memory swap operation which is an overhead on the system.

It's true that first fit is faster than best and worst fit's but just like worst fit we need to do memory swap in order to allocate memory to the 4'th process but in best fit case we do not need any memory swap.

Question 5)

hit ratio $\rightarrow 80\%$

set associative time $\rightarrow 50 \text{ ns}$

Memory access time $\rightarrow 750 \text{ ns}$

②

$$\text{EAT} = \frac{80}{100} \times$$

With hit ratio:

$$\underbrace{\text{search on set associative time}}_{50} + \underbrace{\text{memory access time}}_{750} = 800 \text{ ns}$$

with miss ratio:

$$\underbrace{\text{search on set}}_{50} + \underbrace{\text{memory access time (for copying data from memory to TLB)}}_{750} + \underbrace{\text{memory access time (to get the required data)}}_{750}$$

$$= 1550 \text{ ns}$$

$$\Rightarrow \text{EAT} = \frac{80}{100} \times 800 + \frac{20}{100} \times 1550 = 950 \text{ ns}$$

(b) for n-level paging the EAT is

$$P(\text{TLB Access-time} + \text{Mem Access time}) + (1-P)(\text{TLB-Access time} + (n+1) \times \text{Memory Access time})$$

P = hit ratio

n = n-level paging

for 2 level paging

$$\Rightarrow \frac{80}{100} (50 + \overset{800}{750}) + \frac{20}{100} (50 + \overset{2300}{3} \times 750)$$

$$= \underline{1100 \text{ ns}}$$
